**Introduction**

NWA 856: (Djel ibone)

- Basaltic shergottite
- Discovered in South Morocco in April, 2001 [1]
- Found as single stone of 320 gm [1]
- Fresh, fine grained
- Covered with thin black-fusion crust
- Highly fractured
- Terrestrially less weathered as a desert find [1]
- Crystallization age: 150 ± 2 Ma (Rb-Sr isotope system) and 186 ± 24 Ma (Sm-Nd isotope system) [2]
- Bulk rock oxygen isotopes: $\delta^{17}O = +3.09 \%$, $\delta^{18}O = +5.03 \%$, $\Delta^{17}O = +0.47 \%$ [1]

**Objective**

The purpose of this study is to constrain the crystallization history of NWA 856 using textural observations, crystallization sequence modeling and in-situ trace element analysis in order to understand differentiation in shergottite magmatic systems.

**Analytical Techniques**

A polished thin section (15 x 13 x 2 mm) was used for EDX-elemental mapping by scanning electron microscope (SEM JEOL 7600F). An electron microprobe (EMP) Cameca SX100 was used to obtain in situ major element concentrations of each phase. Both instruments are located in the ABES division of NASA-Johnson Space Center.

Major, minor and trace element abundances in minerals were measured using a Varian 810 inductively coupled plasma mass spectrometer connected to a CETAC LSK-213 laser ablation system (LA-ICP-MS) in the department of Earth and Atmospheric Sciences of the University of Houston. The sizes of the analyzed spots were 20-100 µm in diameter. The software GLITTER was used to calculate concentrations. Analyses were normalized to CaO contents obtained from EMP analyses. Basalt glass BHVO-2G (USGS standard) was used for calibration while BIR-1G (USGS standard) was used as an external standard to monitor accuracy and reproducibility.

**Shock Features**

- Highly fractured
- Maskelynitization
- Pyroxyne dislocations and twins [3]
- Abundant impact melt pockets [4]
- Presence of stishovite and high silica glass [1, 4]

**Crystallization Sequence**

The crystallization sequence of NWA 856 is derived from textural relationships and compared to results from MELTS simulations [5] using NWA 856 bulk composition from [1] as initial composition. MELTS simulation, result in the same crystallization sequences at 4 kbar and 5 kbar and those run under fractionation conditions are most consistent with our textural analysis.

![Figure 10: Crystallization sequence based on MELTS simulation of isobaric equilibrium and fractional crystallization.](image10)

**In-Situ Trace-Elements**

NWA 856 is an enriched basaltic shergottite with flat rare earth element (REE)-pattern similar to Shergotty and Zagami [1]. The absence of positive Ce-anomalies and lower contents of Cs, Ba and Sr in all phases when compared to other desert finds indicate that NWA 856 is the least affected by terrestrial weathering and alteration.

**Discussion and Conclusion**

The results of petrography, EMP, LA-ICP-MS analyses and MELTS simulations are consistent with the findings of [1]. Pyroxene and spinel began to crystallize first. This was followed by a multistage crystallization sequence with plagioclase formation and final crystallization of phosphates and ilmenite. Pyroxene cores are not disturbed by alteration or shock but plagioclase was shocked into maskelynite with local incorporation of phosphates. NWA 856 closely resembles Shergotty and Zagami, but the lack of mesostasis, larger grain size, an abundance of impact melt pockets and minimal terrestrial weathering separate NWA 856 from any other basaltic shergottites.
