A New Global Database of Mars River Dimensions

Edwin S. Kite1,* (kite@uchicago.edu), David P. Mayer1,2, Casey J. Duncan3, Deirdre Edward1

The scale of ancient Mars rivers – their paleochannel widths and meander wavelengths – is a proxy for past river discharge. Evidently, divided by drainage area, yields runoff production, which is a key parameter for selecting between climate models (e.g. rain versus snowmelt). Repeated ArcGIS traces are merged and analyzed in MATLAB. 172 drainage areas are represented. – ~83% of sites have HiRISE coverage (~60% of those with HiRISE anaglyphs or HiRISE DTMs) – an advance over the pioneering THEMIS study of Irwin et al., Geology, 2005

Two main biases in the database:
(1) Only well-preserved channels and drainage areas are included.
(2) We measured the largest visible channels in a catchment.

Rivers on Mars were wider than rivers on Earth for the same drainage area

The main surprise so far: Channels are frequently too big (relative to their drainage area) to be easily reconciled with a seasonal-snowmelt climate. As expected from Earth data, scatter is high. At Earth sites, the width of flat-topped ridges can record channel-belt width (not channel width). On Mars, width-inferred and wavelength-inferred paleodischarges agree, consistent with the interpretation that well-preserved flat-topped sinuous ridges record channel width.

Findings:

Evidence for regional variations

Discharge Q inferred from wavelength λ:

Discharge Q inferred from width w:

The main surprise so far: Channels are frequently too big (relative to their drainage area) to be easily reconciled with a seasonal-snowmelt climate. As expected from Earth data, scatter is high. On Mars, width-inferred and wavelength-inferred paleodischarges agree, consistent with the interpretation that well-preserved flat-topped sinuous ridges record channel width.

Fine grain sizes, or extreme runoff production on Early Mars?

We have ruled out the possibilities that my observations result from (1) limited image resolution, post-eruption modification, flash-snowmelt due to reentry heating from distant impact ejecta, dam-overtopping, kant-like modification of paleochannels, or misinterpretation of debris-flow deposits. We might be measuring stratigraphic risers or channel deposits at some sites, but not most. Published work on Earth permafrost-river hydraulic geometry does not support a large permafrost correction. Two possibilities remain:

Do the flare tops of sinuous ridges measured from orbit correspond to channel-belt widths, or channel widths? Sinuous ridges near Green River in SE Utah preserve channel deposits and point-bar deposits. At this site, channel deposits preserved within sinuous ridges can be less than the width of the flat top of the ridge, and in some interpretations the width of the flat top of the ridge corresponds to channel-belt width, not a channel width. These Earth analog data are a warning against over-interpreting HiRISE DTMs, because the decisive grain-size and bedset-thickness measurements are very difficult from orbit. For many Mars river deposits, the simplest interpretation of sinuous-ridge width is nevertheless that ridge-top width corresponds to inverted channel width. This is because (1) sandblasting-away of floodplain deposits allows diagnostic bedforms, e.g. lateral-accretion deposits, to be recognized from orbit; (2) agreement between meander-wavelengths and paleochannel widths allows cross-checking; (3) rivers can transition from negative-relief valley floors to positive-relief channel floors, which decreases the likelihood that either is an artifact.

Acknowledgements: Particular thanks to Jonathan Sneed and Sam Holm for contributing to fieldwork. Thanks to Marion Chan for logistic and intellectual support for fieldwork. Thank you to Sharon Wilson, Caleb Fasset, Joel Davis, and Maria Palucis, who each shared unpublished work. We acknowledge useful discussions with Becky Williams, Robert Jacobsen, Ben Cardenas, Alan Howard, Devin Burr, Tim Goudge, Alastair Hayden, Caleb Fasset, Nicolas Mangold, David Mohrig, Ben Cardenas, Roman diBiase, and especially Ross Irwin. Grants: NASA (NNX15AM49G, NNX16AG55G).

Author contributions: E.S.K. analyzed Mars data and supervised fieldwork. D.P.M. built the Mars GIS, and the Mars DTMs, for the project. C.J.D. collected the drone data and built the Earth DTMs. D.E. analyzed drone data.
